Abstract: In this study, we demonstrated the antioxidant and protective properties of crude extract and fractions from Fructus Ligustri Lucidi (FLL) against hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)-induced oxidative damage in SH-SY5Y cells. The contents of the phytochemical profiles from FLL crude extracts and fractions were determined by spectrophotometric methods and high performance liquid chromatography using a photodiode array detector. FLL crude extract possessed appreciable scavenging capacity against 1,1-diphenyl-2-picrylhydrazyl and H<sub>2</sub>O<sub>2</sub>. The ethyl acetate (EtOAc) fraction was the most active fraction in scavenging free radicals and H<sub>2</sub>O<sub>2</sub>. Following exposure of cells to H<sub>2</sub>O<sub>2</sub>, there was a marked decrease in cell survival and intracellular antioxidant enzymes. Intracellular oxidative stress, the level of lipid peroxidation, and caspase-3 activity were increased when cells was exposed to H<sub>2</sub>O<sub>2</sub>. Simultaneous treatment with the EtOAc fraction blocked these H<sub>2</sub>O<sub>2</sub>-induced cellular events. Hydroxytyrosol and salidroside are the major components of the EtOAc fraction. These results show that the EtOAc fraction of FLL is enriched in phenol and contains tyrosol-related derivatives and that this fraction exerts protective effects against H<sub>2</sub>O<sub>2</sub> toxicity via its free radical scavenging activity and ability to elevate the levels of antioxidant enzymes.

Dear **Editor-in-Chief**:

We submit this manuscript which entitled "**Antioxidant phenolic profile from ethyl acetate fraction of Fructus Ligustrum Lucidi with protection against hydrogen peroxide-induced oxidative damage in SH-SY5Y cells**" for publication in the *Food and Chemical Toxicology*.

Fructus Ligustrum Lucidi (FLL) is commonly used for curing hepatitis and aging-associated symptoms by traditional Chinese physicians for centuries. This study evaluated the antioxidant properties and components of FLL, and further demonstrated their protective effects against hydrogen peroxide-induced oxidative damage in SH-SY5Y cells. We found FLL partitioned with ethyl acetate has best antioxidant properties *in vitro* and enriched phenolic contents. It further protects oxidative damage caused by hydrogen peroxide in part from the upregulation of intracellular antioxidant status and the inhibition of caspase-3 activation. Hydroxytyrosol and salidroside are major components of ethyl acetate fraction of FLL. Six graphics (including one supplementary graph) and three tables are presented in this manuscript.

This paper is an original article and has not been submitted elsewhere for publications. I hope that it will be considered for publication in the *Food and Chemical Toxicology*. Thank you very much for your help and wish to hear from you very soon.

Sincerely Yours,

Chi-Rei Wu

## **Food and Chemical Toxicology**

Antioxidant phenolic profile from ethyl acetate fraction of Fructus Ligustrum Lucidi with protection against hydrogen peroxide-induced oxidative damage in SH-SY5Y cells

Dear editor,

Thank you for your useful comments and suggestions on the language and the structure of our manuscript. We have modified the manuscript accordingly, and the detailed corrections are listed below point by point:

1) Research highlights provided should be indicated by bullet points, with a maximum of 85 characters (including spaces) pre bullet point.

[We have corrected research highlights and re-upload the corrected “Research highlight” file.](#)

2) Abstract and a list of keywords should be provided before the introduction section.

[We have added the abstract and keywords before the “introduction” section and re-upload the corrected “manuscript” file.](#)

3) Figure 5 is not cited in the text.

[We have cited Figure 5 in the corrected “manuscript” file.](#)

4) Please check the suggested reviewers instructions - there should be 4 reviewers of which 2 should be from a different country to the corresponding author. E-mail addresses containing hotmail, gmail, and yahoo accounts should not be used.

[We have changed two reviewers.](#)

Thank you very much for your help and the manuscript has been resubmitted to your journal. We look forward to your positive response.

Sincerely Yours,

Chi-Rei Wu

**Declarations**

*Food and Chemical Toxicology* requires that all authors sign a declaration of conflicting interests. If you have nothing to declare in any of these categories then this should be stated.

**Conflict of Interest**

A conflicting interest exists when professional judgement concerning a primary interest (such as patient's welfare or the validity of research) may be influenced by a secondary interest (such as financial gain or personal rivalry). It may arise for the authors when they have financial interest that may influence their interpretation of their results or those of others. Examples of potential conflicts of interest include employment, consultancies, stock ownership, honoraria, paid expert testimony, patent applications/registrations, and grants or other funding.

**Please state any competing interests**

No competing interest.

**Funding Source**

All sources of funding should also be acknowledged and you should declare any involvement of study sponsors in the study design; collection, analysis and interpretation of data; the writing of the manuscript; the decision to submit the manuscript for publication. If the study sponsors had no such involvement, this should be stated.

**Please state any sources of funding for your research**

We have described all funding in the "Acknowledgment" Section of our manuscript.

## Main text

### 1. Introduction

For centuries, Fructus Ligustri Lucidi (FLL) has been commonly used by traditional Chinese physicians for curing hepatitis and aging-associated symptoms. Harman (2006) suggested that the aging process is due to oxidative stress cascades, including attack from reactive oxygen species (ROS) and deficiency in intracellular antioxidative defense. In fact, many chronic diseases, including neurodegenerative diseases and cardiovascular diseases, may be caused by intracellular oxidative damage to biomolecules, such as carbohydrates, proteins, lipids and DNA, via ROS (Butterfield and Sultana, 2008; Fearon and Faux, 2009). Minimizing the cellular redox imbalance may be one of the most important approaches to the prevention of these aging-associated diseases. Antioxidants scavenge free radicals, which initiate and propagate oxidative chain reactions, and thus prevent intracellular oxidative damage (Valko et al., 2007). Natural antioxidants, such as phenols and flavonoids, have been revealed to possess multiple pharmacological activities, including neuroprotective and anti-aging activities, via their antioxidant properties (Uttara et al., 2009).

Recent pharmacological studies have indicated that FLL possesses hepatoprotective and antidiabetic activities (Gao et al., 2009; Yim et al., 2001), and some reports have indicated that FLL possesses antioxidant activities (He et al., 2001; Li et al., 2007). Therefore, its hepatoprotective and antidiabetic activities may be due to improvements intracellular antioxidative status, including glutathione regeneration and upregulation of antioxidant enzymes (Gao et al., 2009; Yim et al., 2001). Its active components have been recognized as triterpenoids, secoiridoids and the glycosides of these compounds (Gao et al., 2009; Li et al., 2007; Yim et al., 2001).

In this paper, we evaluated the antioxidant and radical scavenging activities of FLL crude extract and fractions by several different *in vitro* antioxidant test systems, such as the 1-diphenyl-2-picrylhydrazyl (DPPH) radical-scavenging assay, the trolox equivalent antioxidant capacity (TEAC) assay, the reducing power assay and the iron-chelating activity (ICA) assay. Because ROS play an important role in intracellular oxidative damage, we also evaluated the effects of FLL crude extract and fractions on scavenging hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and hydroxyl radical and inhibiting lipid peroxidation by the Fenton reaction. We further attempted to demonstrate the possible protective effects of FLL crude extract and fractions against H<sub>2</sub>O<sub>2</sub>-induced oxidative damage in SH-SY5Y cells. Based on earlier reports on the bioactive components of FLL (Gao et al., 2009; He et al., 2001; Li et al., 2007; Yim et al., 2001), the contents of all phytochemical profiles, including phenols, flavonoids, phenylpropanoids, iridoids and triterpenoids, from FLL crude extract and fractions were determined by spectrophotometry and high performance liquid chromatography-photodiode array detector (HPLC-DAD).

## 2. Materials and methods

### 2.1. Preparation of herb extract and fractionation

FLL was purchased from an herb supplier in Taiwan. FLL (6 kg) was extracted five times with 50% ethanol. The resultant extract was combined and concentrated under reduced pressure to obtain 1,330 g of residue (22.7%). The crude extract was suspended in water and then partitioned successively with four-times-volume amounts of chloroform, ethyl acetate and *n*-butanol. Each fraction was evaporated in a vacuum to obtain the chloroform (CHCl<sub>3</sub>, 31.3 g, 2.35%), ethyl acetate (EtOAc, 61.3 g, 4.61%), *n*-butanol (BuOH, 206 g, 15.49%) and water fractions (852.3 g, 64.08%).

## 2.2. Chemicals

2-deoxyribose, 2,2'-azino-bis-3-ethylbenzthiazoline-6-sulfonic acid (ABTS), 2',  
7'-dichlorofluorescein diacetate (DCFH-DA), 2-vinylpyridine (2-VP),  
3-(2-pyridyl)-5,6-diphenyl-1,2,4-triazine-4',4''-disulfonic acid (ferrozine),  
3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium (MTT),  
5,5'-dithio-bis(2-nitrobenzoic) acid (DTNB),  
6-hydroxy-2,5,7,8-tetramethy-chroman-2-carboxylic acid (trolox), acridine orange  
(AO), aluminum nitrate, ascorbic acid, betulin, (+)-catechin, DPPH, ferric chloride,  
ferrous sulfate heptahydrate, Folin-Ciocalteu's reagent, reduced glutathione (GSH),  
glutathione peroxidase (GPx), glutathione reductase (GR), homovanillic acid (HVA),  
horseradish peroxidase (HRPase), *p*-hydroxybenzoic acid (HBA), malodialdehyde  
(MDA), nitroblue tetrazolium chloride (NBT), oxidized glutathione (GSSG),  
potassium acetate, potassium ferricyanide, potassium persulfate, quercetin, sodium  
carbonate, superoxide dismutase (SOD), thiobarbituric acid (TBA), triethanolamine  
and trichloroacetic acid (TCA) were purchased from Sigma-Aldrich Chem. Corp. (St.  
Louis, MO, USA). Aucubin, betulinic acid, hydroxytyrosol, nuhenzide, oleanolic acid,  
oleuropein, protocatechuic acid (PCA), quercitrin, salidroside, tyrosol, ursolic acid  
and verbascoside standards were purchased from Extrasynthese (Lyon Nord,  
GENAY, France). H<sub>2</sub>O<sub>2</sub> and *o*-phosphoric acid were purchased from Merck  
(Darmstadt, Germany). All solvents were HPLC grade and also purchased from  
Merck.

## 2.3. Determination of antioxidant and radical scavenging activities

### 2.3.1. Radical scavenging activity assay

1 The DPPH radical scavenging capacity assay was performed as described  
2 previously (Wu et al., 2011b). Briefly, 25  $\mu$ L of sample solution or catechin standard  
3 was pipetted into each well, and then 175  $\mu$ L of 300  $\mu$ M DPPH solution was added.  
4  
5 The absorbance of the mixture was read at 517 nm with a spectrophotometric  
6  
7 microplate reader (Bio-Tek, PowerwaveX340, Winooski, VT) after a 30-min  
8  
9 incubation at 25 °C. The results were expressed as mmol of (+)-catechin equivalents  
10  
11 per gram of sample.  
12  
13  
14  
15  
16  
17  
18  
19

### 20 2.3.2. TEAC assay

21 TEAC was measured by the ABTS radical scavenging assay (Wu et al., 2011b).  
22  
23 First, ABTS radical was prepared by reaction of 8 mM ABTS solution and 8.4 mM  
24  
25 potassium persulfate solution at a ratio of 2:1, respectively. After storage in the dark  
26  
27 at RT for 12-16 h, the radical solution was further diluted with ethanol until an initial  
28  
29 absorbance value of  $0.70 \pm 0.05$  at 734 nm was reached. One hundred seventy-five  $\mu$ L  
30  
31 of diluted ABTS solution was mixed with 25  $\mu$ L of sample solution or trolox  
32  
33 standard. The results were expressed as TEAC values.  
34  
35  
36  
37  
38  
39  
40  
41

### 42 2.3.3. Reducing power assay

43 Reducing power was determined spectrophotometrically by the formation of Perl's  
44  
45 Prussian blue colored complex (Wu et al., 2011b). First, 25  $\mu$ L of sample solution was  
46  
47 loaded into each well. Then 100  $\mu$ L of 50  $\mu$ M phosphate buffer (pH 6.6) and 0.1%  
48  
49 (w/v) potassium ferricyanide was added. After incubation at 50 °C for 20 min, 100  $\mu$ L  
50  
51 of 1% (w/v) TCA was added. Finally, 200  $\mu$ L of the mixture solution was transferred  
52  
53 into a new 96-well plate and mixed with 25  $\mu$ L of 5 mM ferric chloride. Absorbance  
54  
55  
56  
57  
58  
59  
60  
61

1 of the reaction mixture was read spectrophotometrically at 700 nm. The results were  
2 expressed as relative reducing equivalents of ascorbate.  
3

#### 4 5 6 7 *2.3.4. H<sub>2</sub>O<sub>2</sub> scavenging activity assay*

8  
9 H<sub>2</sub>O<sub>2</sub> scavenging activity was performed as described previously (Wu et al.,  
10 2011b). The reaction mixture contained 25 mM phosphate buffer (pH 7.4), 0.5 mM  
11 H<sub>2</sub>O<sub>2</sub> and sample solution or Trolox standard in a total volume of 150 µL. After  
12 incubation for 5 min at RT, 50 µL of 5 mM HVA and 8 U/mL HRPase were added,  
13  
14 mixed and incubated for 25 min at RT. The fluorescence intensity was measured at an  
15  
16 excitation of 315 nm and an emission of 425 nm using a fluorescence microplate  
17  
18 reader (Bio-Tek, FLX800, Winooski, VT). The results were expressed as µmol of  
19  
20 trolox equivalents per gram of sample.

Hydroxyl radical scavenging activity was monitored using the 2-deoxyribose method (Halliwell et al., 1987). Briefly, the ferrous iron solution and EDTA were premixed, and then added to the assay mixture solution. The assay mixture solution contained 2.8 mM 2-deoxyribose, 20 µM ferrous ion solution, 100 µM EDTA and sample in a total volume of 1 mL of potassium phosphate buffer (10 mM, pH 7.4). The reaction was initiated by the addition of 1.42 µM H<sub>2</sub>O<sub>2</sub> and 100 µM ascorbate, and then incubated at 37°C for 30 min. At the end of the incubation period, 1% (w/v) TBA and 2.8% (w/v) TCA were added. This solution was heated for 30 min in a boiling water bath, cooled and measured at an absorbance of 532 nm, which is a marker for deoxyribose damage (Wu et al., 2011b). The reciprocal absorption values obtained for different concentrations were plotted against the concentrations of the

1 sample solution, and, from the graph, the second order rate constants were calculated  
2 with a rate constant of  $3 \times 10^9 \text{ M}^{-1} \text{ S}^{-1}$  (Halliwell et al., 1987).  
3  
4  
5  
6

#### 7 *2.4. ICA assay*

8  
9 This method is based on the formation of the ferrozine- $\text{Fe}^{+2}$  colored complex  
10 which has a strong absorbance at 562 nm. The reaction mixture solution contained  
11 sample, 50  $\mu\text{M}$  ferrous sulfate and 300  $\mu\text{M}$  ferrozine. After incubation at 25 °C for 10  
12 min, the absorbance was recorded. The percentage of inhibition of the ferronize- $\text{Fe}^{+2}$   
13 complex formation was calculated in the same way as in our previous report (Wu et  
14 al., 2011b).

#### 27 *2.5. Lipid peroxidation inhibition assay*

28  
29 Rat brain homogenate was used as a source of polyunsaturated fatty acids for  
30 determining the extent of lipid peroxidation. Whole brain was homogenized (100  
31 mg/mL) in ice-cold 0.1 M phosphate buffer (pH 7.4), and then brain homogenate was  
32 centrifuged at 10,000 rpm for 15 min at 4 °C. The reaction mixture consisted of brain  
33 homogenate, 1 mM ferrous sulfate, 5 mM ascorbic acid and sample solution. The  
34 reaction solution was incubated in a shaking water bath in an open tube. After  
35 incubating at 37 °C for 30 min, the thiobarbituric acid reactive substance (TBARS)  
36 test was performed by rapidly adding 1.2% (w/v) TBA and 10% TCA. Then, the tubes  
37 were incubated at 90 °C for 60 min. After cooling, the system was centrifuged at  
38 3,000 rpm for 10 min and the absorbance of the supernatant was determined at 532  
39 nm (Wu et al., 2011b). The absorbance was recorded against blanks prepared in the  
40 same way as the experimental samples but without homogenate.

## 2.6. Determination of the amount of antioxidant compounds

### 2.6.1. Determination of total phenol content

The total phenol content was assayed as described in our previous paper (Wu et al., 2011b). This method is based on the formation of blue-colored products by redox reaction with Folin-Ciocalteu's reagent. The absorbance of the colored solution at 725 nm is proportional to the total phenol concentration. The total phenol concentration of the samples was expressed as mg of catechin equivalents per gram of sample.

### 2.6.2. Determination of flavonoid content

The flavonoid content was also assayed by a 96-well microtiter spectrophotometric method at 415 nm (Wu et al., 2011b). This method is based on the formation of colored products by flavonoids with aluminum salt. The absorbance of the colored solution is proportional to the total flavonoid concentration. The total flavonoid concentration of the samples was expressed as mg of quercetin equivalents per gram of sample.

### 2.6.3. Determination of phenylpropanoid content

The total phenylpropanoid content was determined by a 96-well microtiter spectrophotometric method at 525 nm (Wu et al., 2011b). Briefly, 150  $\mu$ L of sample solution was pipetted into each well, and then 50  $\mu$ L of 0.5 N HCl, 50  $\mu$ L of Arnow reagent (containing 5% (w/v) sodium nitrate and 5% sodium molybdate) and 50  $\mu$ L of 2N NaOH were added. After incubation at 25 °C for 10 min, the absorbance was read. The absorbance of the colored solution is proportional to the total phenylpropanoid concentration. The total phenylpropanoid concentration of the samples was expressed as mg of verbascoside equivalents per g of sample.

#### 2.6.4. Determination of total iridoid content

The total iridoid concentration was determined by a 96-well microtiter spectrophotometric method at 609 nm (Wu et al., 2011b). Twenty-five  $\mu\text{L}$  of sample solution was pipetted into each well, and then 250  $\mu\text{L}$  of Trim-Hill reagent (acetic acid:0.2%  $\text{CuSO}_4\cdot\text{HCl}$  at a ratio of 10:1:0.5, respectively) was added. After heating at 100 °C for 5 min, the absorbance was read. The absorbance of the colored solution is proportional to total iridoid concentration. The total iridoid concentration of the samples was expressed as mg of aucubin equivalents per g of sample.

#### 2.6.5. Determination of triterpenoids and phenolic compounds by HPLC-DAD

FLL crude extract and fractions were dissolved in methanol and then filtered with a 0.22  $\mu\text{m}$  filter. Stock solutions of the standards were prepared in methanol to final concentrations of 1 mg/mL. All standard and sample solutions were injected into 10  $\mu\text{L}$  in triplicate. The Shimadzu VP series HPLC system and Shimadzu Class-VP<sup>TM</sup> chromatography data system were used. All chromatographic operations were carried out at 25 °C. The chromatographic peaks of triterpenoids and phenolic compounds were confirmed by comparing their retention times and UV spectra.

A LiChrospher® RP-18e (250  $\times$  4 mm, 5  $\mu\text{m}$ ) column (Merck KGaA, Darmstadt, Germany) was used. Chromatographic separation of phenolic compounds, including HBA, hydroxytyrosol, oleuropein, PCA, salidroside, tyrosol, quercitrin and verbascoside, was carried out using a two-solvent system. Solvent A is 100% methanol, and solvent B is 0.2% acetic acid at pH=3.23. The analyses were performed by a gradient program. The conditions were as follows: initial condition of 90% solvent B, 0-10 min changed to 75% solvent B, 10-16 min changed to 72% solvent B,

16-22 min changed to 60% solvent B, 22-30 min changed to 57% solvent B, 30-40 min changed to 60% solvent B and 40-42 min changed to 65% solvent B. Signals were detected at 280 nm. The concentrations used for the calibration of reference phenolic compounds were between 10 and 200 µg/mL.

A Supelco Discovery® C18 (150 × 4.6 mm, 5 µm) column (Sigma-Aldrich Co., USA) was used for triterpenoids, including betulin, betulinic acid, oleanolic acid and ursolic acid. The HPLC-DAD conditions were the same as in our previous report (Wu et al., 2011a). The concentrations used for the calibration of reference triterpenoid compounds were between 10 and 250 µg/mL.

## 2.7. *Protective effects of H<sub>2</sub>O<sub>2</sub>-induced neuronal damage in SH-SY5Y cells*

### 2.7.1. *Cell culture and treatment*

Human neuroblastoma SH-SY5Y cells were cultured in DMEM supplemented with 10% fetal bovine serum, 100 units/mL penicillin and 100 µg/mL streptomycin in a water-saturated atmosphere of 5% CO<sub>2</sub> at 37 °C. Experiments were carried out 24 h after cells were seeded in 96-well sterile clear-bottom plates, 60 mm or 90 mm dish. Cells were plated at an appropriate density according to the scale of each experiment. H<sub>2</sub>O<sub>2</sub> (1 mM) or vehicle, as control, was used in the study, described below, after a 16-h exposure. All samples were simultaneously treated with H<sub>2</sub>O<sub>2</sub>. The stock solutions of FLL crude extract, EtOAc fraction and trolox were prepared using DMSO, filtered with a 0.22 µm sterile filter and then diluted with DMEM without phenol red.

### 2.7.2. *MTT assay*

1 The MTT assay was performed to study cell survival. This assay is based on the  
2 ability of living cells to reduce MTT to insoluble formazan. The amount of formazan  
3 produced reflects cell viability. Briefly, 16 h after treatment with H<sub>2</sub>O<sub>2</sub>, the medium  
4 was replaced and MTT was added to each well. The cells were incubated for 2 h at  
5 37°C under a 5% CO<sub>2</sub> atmosphere. The cells were washed with PBS, and DMSO was  
6 added. After 30 min of stirring, the absorbance was measured at 570 nm using a  
7 microplate reader. The inhibition of MTT reduction indicates the degree of  
8 H<sub>2</sub>O<sub>2</sub>-induced toxicity to cells. Experiments were performed in triplicate in five  
9 independent experiments. Cell viability was expressed as percentage relative to  
10 H<sub>2</sub>O<sub>2</sub>-untreated cells, which served as the control group (designated as 100% viable).  
11  
12 In other world, the results were expressed as percentage of the control.

### 29 *2.7.3. Observation of morphologic changes and AO staining*

31 SH-SY5Y cells were seeded at appropriate densities in a 60-mm dish and  
32 incubated overnight in a water-saturated atmosphere of 5% CO<sub>2</sub> at 37°C. All samples  
33 were treated simultaneously with H<sub>2</sub>O<sub>2</sub>. Cellular morphology was observed 16 h after  
34 H<sub>2</sub>O<sub>2</sub> exposure using a phase-contrast microscope (Nikon, Tokyo). AO staining was  
35 observed by fluorescence microscopy (Nikon, Tokyo). Viable cells have a bright  
36 green nucleus with an intact structure, while apoptotic cells exhibit a bright green  
37 nucleus showing chromatin condensation as dense green areas.

#### 25 *2.7.5. Measurement of intracellular ROS levels*

26  
27 The intracellular ROS level was estimated using the fluorescent probe DCFH-DA.  
28 DCFH-DA readily diffuses through the cell membrane and is enzymatically  
29 hydrolyzed by intracellular esterases to form non-fluorescent 2',  
30 7'-dichlorofluorescein (DCFH), which is then rapidly oxidized to form highly  
31 fluorescent 2',7'-dichlorofluorescein (DCF) in the presence of intracellular ROS,  
32 especially H<sub>2</sub>O<sub>2</sub>. On the day of the experiment, SH-SY5Y cells, at a density of 2 × 10<sup>4</sup>  
33 cells/well, were washed 3 times with Krebs-Ringer-HEPES (KRH) buffer (120 mM  
34 NaCl, 4.7 mM KCl, 2.2 mM CaCl<sub>2</sub>, 10 mM HEPES, 1.2 mM KH<sub>2</sub>PO<sub>4</sub> and 1.2 mM  
35 MgSO<sub>4</sub>, pH 7.4) after removal of the medium, and then were incubated with  
36 DCFH-DA in serum-free medium for 30 min at 37°C under a 5% atmosphere. After  
37 DCFH-DA was removed, the cells were washed 3 times with KRH buffer again and  
38 incubated with DMEM without phenol red containing H<sub>2</sub>O<sub>2</sub>, FLL crude extract (300  
39 µg/mL), EtOAc fraction (50 µg/mL) and trolox (200 µM). The fluorescence of the

4  
5  
6

#### 7 *2.7.6. Measurement of intracellular GSH and GSSG levels*

8  
9 The GSH and GSSG levels were determined described previously (Tsai et al.,  
10 2009). Briefly, the lysates (20 µg/50 µL) and GSH standards were pipetted into each  
11 well of a 96-well plate. The reaction solution included 660 µM DTNB, 900 µM  
12 NADPH and 4.5 U/mL GR and, after addition to each well, was recorded at 405 nm  
13 for 5 min in a microplate reader. GSSG levels in cells were measured by the above  
14 method, except the lysates were pretreated with 2-VP and neutralized with  
15 triethylamine to conjugate cellular GSH. The ratio of GSH/GSSG was calculated as  
16 follows:  $GSH/GSSG = [(total\ glutathione\ levels/\ \mu g\ of\ protein) - (GSSG\ levels/\ \mu g\ of\ protein)] / (GSSG/\ \mu g\ of\ protein)$

#### 34 *2.7.7. Measurement of cellular antioxidant enzymes.*

35  
36 Following incubation for 16 h with H<sub>2</sub>O<sub>2</sub>, SH-SY5Y cells were collected from  
37 culture dishes and sonicated on ice. The solution was centrifuged for 15 min at 4°C to  
38 eliminate cell debris, and the supernatant was used in enzyme activity assays.  
39  
40 Antioxidant enzyme activities including catalase, GPx, GR and SOD were measured  
41 as in our previous report (Tsai et al., 2009). Catalase and SOD activities were  
42 expressed as units per mg of protein. The activities of GPx and GR were expressed as  
43 mU/mg of protein.

#### 56 *2.7.8. Lipid peroxidation assay*

1 Lipid peroxidation was measured with the TBARS assay in cell cultures. Briefly  
2 the lysates (200 µg/100 µL) and MDA standard were pipetted into 1.5 mL tubes, and  
3  
4 a TBA test was performed by rapidly adding 1.2% (w/v) TBA and 10% TCA. Then,  
5  
6 the tubes were incubated at 90 °C for 60 min. After cooling, the system was  
7  
8 centrifuged at 3,000 rpm for 10 min, and the absorbance of the supernatant was  
9  
10 determined at 532 nm (Tsai et al., 2009). The experiments were performed in  
11  
12 triplicate in three independent trials.

29  
30  
31

## 32 3. Results and Discussion

### 33 3.1. Antioxidant and radical-scavenging activities

34 In this study, we first evaluated the free radical scavenging activity of FLL crude  
35  
36 extract and fractions using the DPPH and TEAC assays because these assays are  
37  
38 quick and common *in vitro* antioxidant activity assays. The  $IC_{50}$  values for FLL crude  
39  
40 extract in the DPPH and TEAC assays were 126.16 and 52.32 µg/mL, respectively.  
41  
42 The relative radical scavenging potency of FLL crude extract and all fractions in the  
43  
44 DPPH method (using (+)-catechin) and TEAC assay (using trolox) is shown in **Fig.**  
45  
46 **1(A) and 1 (B)**. The greatest scavenging capacity for both radicals was observed in  
47  
48 the EtOAc fraction, with the other fractions following in decreasing order: BuOH ≅  
49  
50 water > CHCl<sub>3</sub>. Therefore, the EtOAc fraction possessed the best free radical  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1 scavenging properties. It is evident in the literature that the antioxidant activity of  
2 plants is associated with their reducing power, which terminates free radical chain  
3 reactions (Wu et al., 2011b; Zhu et al., 2009). Our results also showed that the most  
4 reducing power among all the fractions was observed in the EtOAc fraction, which is  
5 consistent with its free radical scavenging capacity (**Fig. 1(C)**). Therefore, our results  
6 are consistent with other reports that have found that the antioxidant capacity of  
7 natural plants is associated with their reducing power (Wu et al., 2011b; Zhu et al.,  
8 2009).

### 21 *3.2. ROS scavenging and lipid peroxidation inhibiting activities*

24 ROS, major pathological factors, cause many serious diseases, including  
25 neurodegenerative and cardiovascular disorders (Fearon and Faux, 2009; Uttara et al.,  
26 2009; Valko et al., 2007). Among ROS, H<sub>2</sub>O<sub>2</sub> readily crosses cellular membranes and  
27 gives rise to the highly reactive hydroxyl radical, which is the most reactive and  
28 induces severe damage to adjacent biomolecules (Valko et al., 2007). Thus, H<sub>2</sub>O<sub>2</sub> and  
29 the hydroxyl radical scavenging activity of FLL crude extract and all fractions were  
30 investigated. The IC<sub>50</sub> value for FLL crude extract in the H<sub>2</sub>O<sub>2</sub> scavenging activity  
31 assay was 140.59 µg/mL. The highest H<sub>2</sub>O<sub>2</sub> scavenging activity was observed in the  
32 EtOAc fraction, followed by the BuOH, CHCl<sub>3</sub> and water fractions (**Table 1**).

33 However, the highest second order rate constant for scavenging hydroxyl radical  
34 generated from the Fenton reaction was observed in the CHCl<sub>3</sub> fraction (**Table 1**).

35 Because hydroxyl radicals cause lipid peroxidation by attacking polyunsaturated fatty  
36 acids such as brain tissues, we used rat brain homogenate as the oxidizable  
37 biomolecule target for the Fe<sup>2+</sup>/ascorbate method to investigate the lipid  
38 peroxidation-inhibiting effects of FLL crude extract and all fractions. **Table 1** shows

1 that the lowest  $IC_{50}$  value for the inhibition of  $Fe^{2+}$ /ascorbate-induced lipid  
2 peroxidation was also observed in the  $CHCl_3$  fraction. Because the activity of some  
3 antioxidant compounds may be correlated with iron-chelation (Moran et al., 1997)  
4 when iron acts as a catalyst during lipid peroxidation (Valko et al., 2007), further  
5 investigation of the ICA activity of FLL crude extract and all fractions was carried out.  
6  
7 FLL crude extract at the concentrations used in the hydroxyl radical scavenging and  
8 lipid peroxidation-inhibiting assay showed a 20.9% ion-chelating capacity. Among all  
9 the fractions, the water and  $CHCl_3$  fractions exhibited the highest ion-chelating  
10 capacities (about 49.94 and 36.84%, **Fig. 1(D)**). These results indicate that the EtOAc  
11 fraction inhibited lipid peroxidation in brain homogenate systems by terminating  
12 oxidative chain reactions through its radical scavenging capacity; however, the  
13 inhibitory effects of the water and  $CHCl_3$  fractions on lipid peroxidation may be  
14 partially related to iron chelation. Hence, we suggest that the antioxidant mechanism  
15 of the EtOAc fraction, a major antioxidant fraction from FLL, is possibly due to  
16 oxidative chain termination by radical-scavenging but not iron chelation.

### 39 *3.3. Antioxidant components*

40  
41 Phenolic compounds, the main class of natural antioxidants, have been shown to be  
42 correlated with the antioxidant activities of plants (Wu et al., 2011b; Zhu et al., 2009).  
43 The most widespread and diverse phenolic compounds are flavonoids (Hernandez et  
44 al., 2009). Phenylpropanoids, intermediates in the biosynthesis of flavonoids and  
45 other phenolic compounds, also possess antioxidant activities (Korkina, 2007).  
46 Moreover, some researchers have indicated that secoiridoids and their glycosides are  
47 the active components of FLL that scavenge DPPH and APPH radicals (He et al.,  
48 2001; Li et al., 2007). Thus, by spectrophotometric methods, we first measured the  
49

64  
65

1 amount of total phenols, flavonoids, phenylpropanoid glycosides and iridoid  
2 glycosides in FLL crude extract, which were equivalent to 95.16 mg of catechin, 7.52  
3 mg of quercetin, 149.14 mg of verbascoside and 4.75 mg of aucubin, respectively.  
4  
5 The EtOAc fraction had the highest content of phenolic compounds, including  
6 flavonoids and phenylpropanoid glycosides; however, the CHCl<sub>3</sub> fraction had the  
7 highest iridoid content among all the fractions (**Table 2**). Some reports have indicated  
8 that oleanolic acid may be an active component of FLL with respect to its antidiabetic  
9 and hepatoprotective effects (Gao et al., 2009; Yim et al., 2001). We also found that  
10 FLL crude extract contained 2.13 mg/g of betulinic acid, 3.36 mg/g of oleanolic acid  
11 and 2.26 mg/g of ursolic acid (**Table 2**). There is lack of betulin in FLL crude extract,  
12 which is inconsistent with our previous result from the leaves of *Ligustrum lucidum*  
13 (Wu et al., 2011a). Thus, we suggest that the various parts of *Ligustrum lucidum*  
14 contain different types of triterpenoids. The CHCl<sub>3</sub> fraction had the higher amounts of  
15 three triterpenoids than other fractions (**Table 2**). The relationship between  
16 antioxidant potency parameters and the amount of antioxidants was calculated for all  
17 the FLL fractions by Pearson's test. Among all the antioxidant assays, only DPPH,  
18 TEAC and reducing power showed high correlation coefficients ( $r=0.95$ ,  $p < 0.05$  for  
19 DPPH vs TEAC;  $r=0.98$ ,  $p < 0.01$  for DPPH vs reducing power;  $r=0.98$ ,  $p < 0.01$  for  
20 reducing power vs TEAC), suggesting that the antioxidant activities of FLL are  
21 closely related to their hydrogen-donor capacity. In agreement with other reports (Wu  
22 et al., 2011b; Zhu et al., 2009), our assay found total phenol content among all  
23 phytochemical profiles to be positively and highly correlated with DPPH ( $r = 0.96$ ),  
24 TEAC ( $r = 0.95$ ) and reducing power ( $r = 0.96$ ). However, the tendency in the FLL  
25 fractions to contain triterpenoids and iridoids is inconsistent with their antioxidant  
26 activities. Hence, we suggest that phenolic compounds (mainly flavonoids and  
27  
28

1 phenylpropanoids) are major determinants of these antioxidant activities from FLL,  
2 although some secoiridoid compounds isolated from FLL possess radical scavenging  
3 activity (He et al., 2001; Li et al., 2007). In fact, some flavonoid and phenylpropanoid  
4 compounds isolated from other *Ligustrum* plants possess antioxidant and  
5 antimutagenic effects *in vitro* (Nagy et al., 2009; Zhu et al., 2009). Furthermore, our  
6 chromatographic result from HPLC-DAD showed that the EtOAc fraction mainly  
7 contained flavonoid derivatives, such as quercitrin (4.82±0.07 mg/g dry weight of  
8 EtOAc fraction), and phenol derivatives, such as hydroxytyrosol, PCA, salidroside,  
9 tyrosol, oleuropein and verbascoside (27.95±0.75, 9.03±0.24, 20.08±0.61, 12.28±0.32,  
10 10.69±0.19, and 9.31±0.21 mg/g dry weight of EtOAc fraction, respectively) (**Figure**  
11 **2**). Hydroxytyrosol and PCA were first identified in FLL, but all of the above  
12 compounds identified in FLL with HPLC-DAD have been shown to possess  
13 antioxidant activities (Di Benedetto et al., 2007; O'Dowd et al., 2004; Yu et al., 2007;  
14 Zhu et al., 2009). Hydroxytyrosol and salidroside content was highest in the EtOAc  
15 fraction. Therefore, the EtOAc fraction may be enriched in phenol, especially  
16 tyrosol-related derivatives, and possess the better antioxidant activity.

#### 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 *3.4. Protective effects of FLL crude extract, the EtOAc and CHCl<sub>3</sub> fractions against* 46 *H<sub>2</sub>O<sub>2</sub>-induced oxidative damage in SH-SY5Y cells*

47  
48  
49  
50 From the above results, we found that the EtOAc and CHCl<sub>3</sub> fractions possessed  
51 a higher H<sub>2</sub>O<sub>2</sub> and hydroxyl radical scavenging potency than the other fractions. H<sub>2</sub>O<sub>2</sub>  
52 is used extensively as an inducer of oxidative stress *in vitro* because its cellular  
53 actions and pathophysiological roles have been well studied. SH-SY5Y human  
54 neuroblastoma cells are highly sensitive to oxidative stressors such as H<sub>2</sub>O<sub>2</sub>. Hence,  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 we evaluated the protective effects of FLL crude extract, the EtOAc and CHCl<sub>3</sub>  
2 fractions against H<sub>2</sub>O<sub>2</sub>-induced cell injury in SH-SY5Y cells with the MTT assay. The  
3  
4 cell viability of SH-SY5Y cells incubated with 1 mM H<sub>2</sub>O<sub>2</sub> for 16 h decreased to  
5  
6 12.4% compared with the control (**Fig. 3(A)**). FLL crude extract, the EtOAc and  
7  
8 CHCl<sub>3</sub> fractions were able to increase cell viability in a concentration-dependent  
9  
10 manner, acting against H<sub>2</sub>O<sub>2</sub>. The EtOAc fraction had the best protective effect  
11  
12 against H<sub>2</sub>O<sub>2</sub>, and the potency at 25 µg/mL is equal to that of trolox at 200 µM.  
13  
14 Furthermore, to confirm the protective effect of FLL crude extract and the EtOAc  
15  
16 fraction against H<sub>2</sub>O<sub>2</sub>-induced cell injury, we observed morphological alterations by  
17  
18 phase-contrast microscopy. Incubation with 1 mM H<sub>2</sub>O<sub>2</sub> for 16 h induced cell  
19  
20 shrinkage and a decrease in cell number. AO staining showed apoptotic  
21  
22 morphological changes, including chromatin condensation and nuclear fragmentation.  
23  
24 FLL crude extract (300 µg/mL) and the EtOAc fraction (50 µg/mL) significantly  
25  
26 alleviated these morphological manifestations and then reversed the apoptotic  
27  
28 morphological changes (**please see supplementary data**). Because H<sub>2</sub>O<sub>2</sub>-induced  
29  
30 apoptosis occurs mainly through the apoptotic caspase pathway and includes  
31  
32 caspase-3 activation (Kim et al., 2000), we assayed the alteration of caspase-3 activity  
33  
34 in SH-SY5Y cells treated with H<sub>2</sub>O<sub>2</sub> plus either FLL crude extract or the EtOAc  
35  
36 fraction. Incubation with 1 mM H<sub>2</sub>O<sub>2</sub> for 16 h increased intracellular caspase-3  
37  
38 activity. Only the EtOAc fraction significantly decreased intracellular capase-3  
39  
40 activity that was increased by H<sub>2</sub>O<sub>2</sub> (**Fig. 3(B)**). Therefore, we suggest that the EtOAc  
41  
42 fraction protects against H<sub>2</sub>O<sub>2</sub>-induced cell injury and apoptosis in SH-SY5Y cells.  
43  
44 The active compounds within the EtOAc fraction acting against H<sub>2</sub>O<sub>2</sub>-induced  
45  
46 oxidative injury may be tyrosol-related compounds, mainly hydroxytyrosol,  
47  
48 salidroside, tyrosol and oleuropein, because there is evidence that these compounds

can scavenge H<sub>2</sub>O<sub>2</sub> and protect against H<sub>2</sub>O<sub>2</sub>-induced oxidative cell death (O'Dowd et al., 2004; Zhang et al., 2007; Zrelli et al., 2011b).

Cell oxidative injury is mainly due to an intracellular imbalance between the generation and elimination of free radicals, caused by the elevation of intracellular radical levels or a decrease in intracellular antioxidant defenses (Butterfield and Sultana, 2008; Valko et al., 2007). GSH, a major intracellular antioxidant, is depleted in intracellular oxidative stress caused by H<sub>2</sub>O<sub>2</sub> and other oxidants (Han et al., 2003). To clarify the protective mechanism of FLL crude extract and the EtOAc fraction against H<sub>2</sub>O<sub>2</sub>-induced cell injury in SH-SY5Y cells, we measured intracellular oxidative stress by DCFH-DA and cellular antioxidant defenses such as GSH and antioxidant enzymes. In DCFH-DA-loaded SH-SY5Y cells, fluorescence intensity gradually increased after 1 mM H<sub>2</sub>O<sub>2</sub> treatment, suggesting an increase in the generation of intracellular ROS. When simultaneously treating with FLL crude extract or the EtOAc fraction, the oxidant burden of SH-SY5Y cells rapidly decreased (**Fig. 3(C)**). Otherwise, incubation with 1 mM H<sub>2</sub>O<sub>2</sub> for 16 h decreased intracellular GSH levels and the ratio of GSH/GSSG in SH-SY5Y cells (**Fig. 4(A)-4(C)**). It also decreased the levels of cellular antioxidant enzymes, such as catalase, SOD, GPx and GR (**Table 3**), and caused an increase in the level of lipid peroxidation in SH-SY5Y cells (**Fig. 3(D)**). This phenomenon is consistent with our previous report (Tsai et al., 2009), which also identified the activation of the caspase pathway and apoptosis (Kim et al., 2000). FLL crude extract and the EtOAc fraction restored intracellular GSH levels, and the ratio of GSH/GSSG decreased by 1 mM H<sub>2</sub>O<sub>2</sub> in SH-SY5Y cells (**Fig. 3(A)-3(C)**). They also reversed the activities of catalase, SOD, GPx and GR, which decreased by 1 mM H<sub>2</sub>O<sub>2</sub> in SH-SY5Y cells (**Table 3**). Only the EtOAc fraction significantly decreased the level of lipid peroxidation increased by H<sub>2</sub>O<sub>2</sub> (**Fig. 3(D)**).

1 It is well known that the protective effects of antioxidants in biological systems are  
2 mainly due to their free radical-scavenging capacity, metal chelating activities and  
3  
4 activation of biological antioxidant enzymes (Kulkarni et al., 2004). Hence, we  
5  
6 suggest that FLL crude extract alleviated H<sub>2</sub>O<sub>2</sub>-induced oxidative damage *via* a  
7  
8 decrease in intracellular oxidative peroxide levels and an increase in the intracellular  
9  
10 GSH levels and cellular antioxidant enzymes. This protective mechanism is the same  
11  
12 as that of reports that demonstrate antidiabetic and hepatoprotective effects of FLL,  
13  
14 which may be mediated by intracellular GSH regeneration and upregulation of  
15  
16 antioxidant status (Gao et al., 2009). The EtOAc fraction, a major active fraction from  
17  
18 FLL, protected H<sub>2</sub>O<sub>2</sub>-induced oxidative damage and apoptosis in SH-SY5Y cells by  
19  
20 reversing the redox imbalance and blocking caspase-3 activation. Its major active  
21  
22 compounds, such as hydroxytyrosol and salidroside, also have been shown to protect  
23  
24 against H<sub>2</sub>O<sub>2</sub>-induced oxidative damage and apoptosis via the modulation of the  
25  
26 mitochondrial membrane, the downregulation of the pro-apoptotic gene Bax, the  
27  
28 upregulation of the anti-apoptotic genes Bcl-2 and Bcl-X(L) and the activation of  
29  
30 AKT, ERK and Nrf2 (Yu et al., 2010; Zhang et al., 2007; Zhu et al., 2011; Zrelli et al.,  
31  
32 2011a).

#### 33 34 35 36 37 38 39 40 41 42 43 44 **4. Conclusion**

45  
46 In conclusion, EtOAc fraction from FLL has the highest phenol content,  
47  
48 especially hydroxytyrosol and salidroside, and exhibits the highest radical scavenging  
49  
50 potency. Its antioxidant activity can be correlated with its reducing power but is not  
51  
52 due to iron chelation, and this antioxidant activity depends on the phenolic  
53  
54 antioxidants but not the triterpenoids or secoiridoids in the fraction, as described in  
55  
56 other reports (He et al., 2001; Li et al., 2007; Yim et al., 2001). The EtOAc fraction  
57  
58  
59

1 has a protective effect against H<sub>2</sub>O<sub>2</sub>-induced oxidative injury and apoptosis *in vitro*,  
2 and this protective mechanism might be related to its ability to decrease intracellular  
3 peroxides (via H<sub>2</sub>O<sub>2</sub> scavenging) and caspase-3 activity, and to its ability to elevate  
4 intracellular GSH levels and antioxidant enzyme activities (**Fig. 5**). Tyrosol-related  
5 compounds, including hydroxytyrosol, salidroside, tyrosol and oleuropein, are its  
6 major active compounds. Furthermore, these compounds could further protect  
7 neuronal damage caused by the amyloid  $\beta$  peptide and MPP(+) (Li et al., 2011;  
8 St-Laurent-Thibault et al., 2011). Hence, we and others (Li et al., 2011;  
9 St-Laurent-Thibault et al., 2011) have found evidence for the potential therapeutical  
10 benefits of FLL, especially its phenol enriched fraction, in treating aging-associated  
11 symptoms and neurodegenerative disorders.

## Legends for Figures

Figure 1. Antioxidant activity of crude extract and fractions from Fructus Ligustri Lucidi (FLL) on (A) DPPH assay, (B) TEAC assay, (C) reducing power assay and (D) ICA assay. Data are expressed as mean  $\pm$  SD ( $n = 4$ ).

Figure 2. HPLC chromatograms of the ethyl acetate (EtOAc) fraction from Fructus Ligustri Lucidi (FLL) at 280 nm. Trace: (A) Standard, (B) EtOAc fraction. 4-HC: 4-hydroxycoumarin as an internal standard.

Figure 3. Effect of crude extract, ethyl acetate (EtOAc) and chloroform (CHCl<sub>3</sub>) fractions from Fructus Ligustri Lucidi (FLL) and trolox on (A) cell viability (MTT assay), (B) the activation of caspase-3, (C) time-course changes in the formation of reactive oxygen species (ROS) caused by H<sub>2</sub>O<sub>2</sub>. The SH-SY5Y cells were treated with 1 mM H<sub>2</sub>O<sub>2</sub> in the presence of these above samples for 16 h at 37 °C. Data are expressed as mean  $\pm$  SEM ( $n = 3$ ). \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , compared with H<sub>2</sub>O<sub>2</sub> group.

Figure 4. Effects of crude extract, ethyl acetate (EtOAc) fraction from Fructus Ligustri Lucidi (FLL) and trolox on (A) cellular glutathione (GSH) levels, (B) oxidized glutathione (GSSG) levels, (C) ratio of GSH/GSSG, and (D) MDA levels. The SH-SY5Y cells were treated with 1 mM H<sub>2</sub>O<sub>2</sub> in the presence of these above samples for 16 h at 37 °C. Data are expressed as mean  $\pm$  SEM ( $n = 3$ ). \*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$ , compared with H<sub>2</sub>O<sub>2</sub> group.

Figure 5. The biological action of Fructus Ligustri Lucidi partitioned with ethyl acetate as a potential antioxidant and protective plant against oxidative stress caused by hydrogen peroxide. Prohibition sign indicates that the inhibitory effect of Fructus Ligustri Lucidi.

**Table 1.** The H<sub>2</sub>O<sub>2</sub>, hydroxyl radical scavenging and lipid peroxidation-inhibition activities of crude extract and fractions of Fructus Ligustrum Lucidi (FLL).

Samples	H <sub>2</sub> O <sub>2</sub> scavenging capacity ( $\mu\text{mol Trolox / g}$ )	Second order rate constant in scavenging hydroxyl radical ( $\times 10^{10}$ )	<i>IC</i> <sub>50</sub> in lipid peroxidation (mg / L)
FLL	450.79 $\pm$ 10.87	2.37 $\pm$ 0.25	17.09 $\pm$ 0.56
CHCl <sub>3</sub> fraction	602.80 $\pm$ 11.78	447.68 $\pm$ 1.33	9.64 $\pm$ 0.77
EtOAc fraction	981.40 $\pm$ 8.75	124.25 $\pm$ 0.98	16.51 $\pm$ 0.28

**Abstract**

In this study, we demonstrated the antioxidant and protective properties of crude extract and fractions from *Fructus Ligustri Lucidi* (FLL) against hydrogen peroxide ( $H_2O_2$ )-induced oxidative damage in SH-SY5Y cells. The contents of the phytochemical profiles from FLL crude extracts and fractions were determined by spectrophotometric methods and high performance liquid chromatography using a photodiode array detector. FLL crude extract possessed appreciable scavenging capacity against 1,1-diphenyl-2-picrylhydrazyl and  $H_2O_2$ . The ethyl acetate (EtOAc) fraction was the most active fraction in scavenging free radicals and  $H_2O_2$ . Following exposure of cells to  $H_2O_2$ , there was a marked decrease in cell survival and intracellular antioxidant enzymes. Intracellular oxidative stress, the level of lipid peroxidation, and caspase-3 activity were increased when cells were exposed to  $H_2O_2$ . Simultaneous treatment with the EtOAc fraction blocked these  $H_2O_2$ -induced cellular events. Hydroxytyrosol and salidroside are the major components of the EtOAc fraction. These results show that the EtOAc fraction of FLL is enriched in phenol and contains tyrosol-related derivatives and that this fraction exerts protective effects against  $H_2O_2$  toxicity *via* its free radical scavenging activity and ability to elevate the levels of antioxidant enzymes.
